Database Management Portal for Breast Cancer Screening

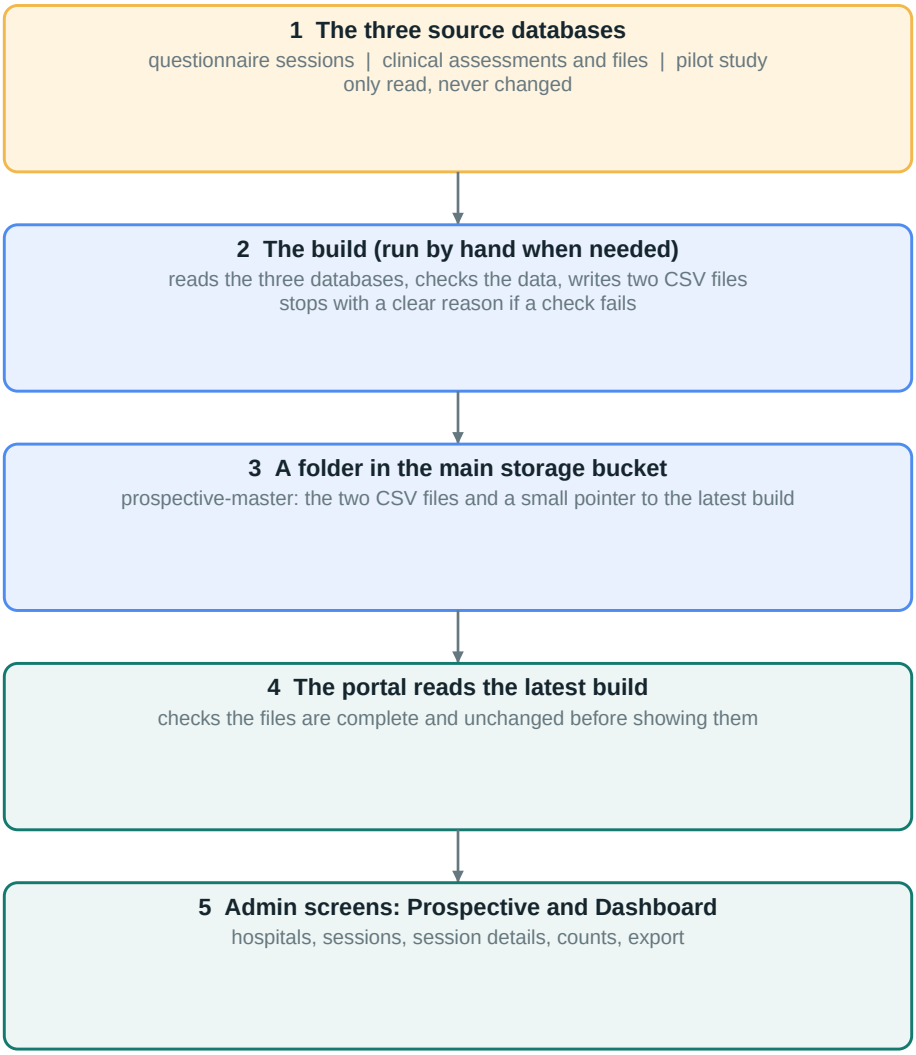
Prospective study and Dashboard

How the data gets into the portal, and what the admin can see

Who	What they can do
Admin	Opens the Prospective screens and the Dashboard. Filters sessions by hospital, CR / DR, BI-RADS, density, completeness and more. Opens one session to see its answers, assessment and files. Exports a list of file paths or a filtered CSV.
Mammo Tech and Radiologist	No access to Prospective or the Dashboard. These screens are for admins only.

Numbers in this document are from the first real build on 30 October 2026 and will change with each new build.

1. How the data gets in



The portal does not look into the live databases while you use it. A separate build collects the data into two CSV files, one row per questionnaire session and one row per file. The portal reads those files. This keeps the live clinical databases safe and makes every screen fast.

- Run the build when you want fresh numbers. It takes about a minute.
- Each build is saved as its own version, so an older one can be brought back if needed.
- The portal refuses a build that is incomplete or has been changed after it was written.

2. What is in the first build

Item	Count
Sessions included	3,466 (portal and pilot)
Files listed	12,749 (mammogram views, reports, ultrasound, annotations, consent photos)
Left out	1,225 sessions that were started but never filled in, and 6 pilot test records without a session
Hospitals	25 hospital records; each pilot site is shown under its parent hospital

3. The rules behind the numbers

- **CR or DR** of a hospital is taken from the hospital record in the database, as given by the doctors. Where a pilot site and its parent hospital differ, each keeps its own value.
- **Machines** are shown as recorded: how many, how many different ones, their names, makes and technology.
- **Test data** is hidden by default and not counted: the Test hospital, Tanuh Foundation, the Pilot Study test site and the BISICON Conference pilot. A tick box shows it when needed.
- **Right and left breast**: in the database the mammogram columns hold the right breast and the ultrasound/biopsy columns hold the left. The build corrects this, so the portal always shows right and left correctly.
- **A complete datapoint** means: consent (not needed for pilot), the questionnaire, all four mammogram views, and BI-RADS and density for both breasts.
- **One woman can have several sessions.** A tick box shows only her latest session.
- **Privacy**: hospital contact names, emails and addresses are not copied into the files. Subject IDs are visible to admins only.

4. The screens

Prospective

- **Summary cards**: sessions, complete datapoints, sessions with a clinician assessment, and CR / DR counts. They follow the filters.
- **Hospitals**: one card per hospital with its CR or DR, machines, and counts of sessions, complete and pilot. Click a card to filter to that hospital and its pilot sites.
- **Sessions table**: search, Portal or Pilot, CR or DR, BI-RADS, density, complete only, latest per woman, include test data. Click a row to open it.
- **Session details**: overview, questionnaire answers and risk results, the clinician assessment, what is complete or missing, and the list of files.
- **Export**: a list of file paths for the filtered sessions, or the filtered table as a CSV.

Dashboard

- **Prospective**: sessions by month, CR vs DR, how complete the data is, BI-RADS and density, and sessions by hospital.
- **Retrospective**: cases received, segmented, in progress, rejected, where the cases are, and who supplied them. These numbers are live.
- The Dashboard updates itself every minute while it is open.

5. Running and updating it

Task	How
See the latest numbers	Open Prospective or Dashboard as an admin.
Refresh the data	Run the build again (from the Cloud Shell, about 15 minutes with the setup steps) and publish it to the same folder. The portal picks up the newest build within a minute.
Change a hospital's CR or DR	Change it on the hospital record in the database, then rebuild.
Mark another site as test data	Add it to backend/src/data/test_hospitals.csv and deploy.
Go back to an older build	Point the pointer file (current.json) at the older build's folder.

6. What comes next

- Open the actual DICOM images and PDF reports from a session inside the portal.
- Decide how often the build is refreshed, for example weekly.
- Decide what management wants on the Dashboard and whether subject IDs should be hidden for some admins.
